The focus on combining like terms is crucial since it lays the groundwork for more complex algebraic operations.

Understanding Combining Like Terms

Combining like terms is a fundamental algebraic skill that involves simplifying expressions by merging terms that have the same variable raised

to the same power. For instance, in the expression $3x + 4x$, both terms are 'like terms' because they share the same variable, x . This process simplifies the expression to $7x$.

Definition and Examples of Like Terms

Like terms are terms that contain the same variable(s) raised to the same power. Understanding this concept is crucial for students as it is the basis for simplification in algebra. Here are some examples:

- $3x$ and $5x$ (both have the variable x)
- $2y^2$ and $7y^2$ (both have the variable y squared)
- $4ab$ and $-2ab$ (both have the variables a and b)

On the other hand, terms like $2x$ and $4y$ are not like terms because they contain different variables. This distinction is important when working with algebraic expressions.

Steps for Combining Like Terms

To effectively combine like terms, students can follow these steps:

1. Identify like terms in the expression.
2. Group the like terms together.
3. Add or subtract the coefficients of the like terms.
4. Rewrite the expression with the combined terms.

For instance, in the expression $2x + 3x - 4 + 5$, the like terms are $2x$ and $3x$, which combine to make $5x$. The constant terms, -4 and $+5$, combine to make $+1$. The simplified expression would be $5x + 1$.
