The Human Skeleton: An Overview

The human skeleton is a complex framework made up of bones, cartilage, and ligaments. It provides structure, support, and protection for the body's organs. The skeleton consists of 206 bones in the average adult, which can be categorized into two main divisions: the axial skeleton and the appendicular skeleton.

Axial Skeleton

The axial skeleton includes the bones of the skull, vertebral column, and rib cage. It serves as the central axis of the body and plays a crucial role in protecting vital organs such as the brain, heart, and lungs.

- **Skull:** Composed of 22 bones, it protects the brain and forms the structure of the face.
- **Vertebral Column:** Made up of 33 vertebrae, it supports the head and protects the spinal cord.
- **Rib Cage:** Consists of 12 pairs of ribs that safeguard the heart and lungs while aiding in respiration.

Appendicular Skeleton

The appendicular skeleton includes the bones of the limbs and the pelvic and shoulder girdles. It allows for movement and interaction with the environment.

- **Pelvic Girdle:** Composed of the hip bones, it connects the lower limbs to the trunk.
- **Shoulder Girdle:** Includes the clavicle and scapula, facilitating arm movement.
- **Limbs:** The upper and lower limbs consist of various bones that enable a wide range of motion.
