Understanding Dilations

Dilations in geometry refer to transformations that produce an image that is the same shape as the original but is a different size. A dilation is defined by a scale factor and a center of dilation. The scale factor determines how much larger or smaller the image will be compared to the original shape. This concept is fundamental in both two-dimensional and three-dimensional geometry and is key to understanding geometric similarity.

Key Concepts of Dilations

When discussing dilations, it is essential to understand the following concepts:

- **Scale Factor:** This is the ratio of the length of a side of the image to the length of the corresponding side of the original figure. A scale factor greater than one enlarges the figure, while a scale factor between zero and one shrinks it.
- **Center of Dilation:** This is the fixed point in the plane about which all points are expanded or contracted. The center can be located inside, outside, or on the figure itself.
- **Similarity:** Dilations create similar figures, meaning the shapes have the same angles and their corresponding sides are proportional.
