Understanding Photosynthesis

Photosynthesis is the biochemical process through which green plants, algae, and some bacteria convert light energy into chemical energy, specifically in the form of glucose. This process is vital for life on Earth as it provides the oxygen we breathe and forms the base of the food chain. The overall reaction of photosynthesis can be summarized by the equation:

In this reaction, carbon dioxide and water are transformed into glucose and oxygen. The process takes place mainly in the chloroplasts of plant cells, which contain chlorophyll, the green pigment responsible for capturing light energy.

The Stages of Photosynthesis

Photosynthesis occurs in two main stages: light-dependent reactions and light-independent reactions (Calvin cycle).

- **Light-dependent reactions:** These occur in the thylakoid membranes and require sunlight. Here, light energy is absorbed by chlorophyll, which excites electrons and leads to the splitting of water molecules, releasing oxygen.
- **Light-independent reactions (Calvin cycle):** These take place in the stroma of the chloroplasts. The ATP and NADPH produced in the light-dependent reactions are used to convert carbon dioxide into glucose.
