Introduction to St. Matthew Island

St. Matthew Island is located in the Bering Sea and is part of the Alaska Maritime National Wildlife Refuge. This remote island is known for its unique geography, including tundra and coastal habitats, which support a variety of wildlife, including a significant population of reindeer. The reindeer were introduced to the island in the 19th century, and their presence has had a profound impact on the ecosystem. Understanding the dynamics of the reindeer's population provides critical insights into the ecological balance of the island.

The Geography of St. Matthew Island

The island spans approximately 50 miles in length and is characterized by rugged terrain and limited vegetation, primarily consisting of mosses, lichens, and low shrubs. The harsh climate, with cold winters and cool summers, creates challenging conditions for both flora and fauna. These geographical features play a crucial role in shaping the reindeer's behavior and survival strategies.

The Importance of the Reindeer

Reindeer are integral to the ecosystem of St. Matthew Island. They serve as a primary herbivore, influencing plant communities and providing a food source for predators. Their grazing patterns can shape the landscape, making them a vital component of the island's ecological framework.

Ecology of Reindeer on St. Matthew Island

The ecology of reindeer on St. Matthew Island is a fascinating subject, revealing how these animals have adapted to their environment over time. The worksheet provides detailed information on various aspects of their ecology, including diet, behavior, and reproduction.

Diet and Foraging Behavior

Reindeer are primarily herbivorous and their diet consists mainly of grasses, herbs, and lichens. On St. Matthew Island, the availability of food sources fluctuates with the seasons, requiring reindeer to adapt their foraging strategies. In winter, they rely heavily on lichens, which are abundant in the tundra, while in summer, they graze on the rich vegetation.

- Summer Diet: Grasses and herbs
- Winter Diet: Lichens and woody plants

Behavioral Adaptations

Reindeer exhibit several behavioral adaptations that enhance their survival in the challenging environment of St. Matthew Island. These include migratory patterns, social structures, and reproductive strategies. The worksheet outlines these adaptations, providing a comprehensive understanding of how reindeer interact with their environment and each other.

Population Dynamics and Historical Context

The history of reindeer on St. Matthew Island is marked by significant population fluctuations, influenced by environmental changes and human impacts. Understanding these dynamics is crucial for conservation efforts and ecological studies.

Historical Population Changes

The introduction of reindeer to St. Matthew Island in 1944 led to a rapid increase in their population. Initially, they thrived due to the lack of natural predators and abundant food sources. However, overpopulation soon became a concern, leading to resource depletion and subsequent population crashes. The worksheet provides data and graphical representations of these changes, allowing students to analyze trends and draw conclusions.

Current Population Status

As of recent assessments, the reindeer population on St. Matthew Island faces various challenges, including climate change and habitat degradation. These factors continue to influence their survival and reproduction rates. Understanding the current status of reindeer is crucial for developing effective conservation strategies.
