## Introduction to Washers and Disks Calculus

Washers and disks calculus is primarily focused on calculating the volume of solids formed by revolving a two-dimensional shape around an axis. The disk method is used when the solid has no hole, while the washer method applies when there is a hole in the center of the solid. Understanding these methods requires a solid grasp of integral calculus, as both techniques utilize definite integrals to find volumes. This section will introduce the basic concepts and lead into more detailed explanations of each method.

## The Importance of Volume Calculations

Volume calculations are essential in various fields, including engineering, physics, and architecture. By

using washers and disks calculus, professionals can accurately determine the volumes of complex shapes that cannot be easily measured. This accuracy is crucial for designing structures, manufacturing materials, and even in scientific research where precise measurements are necessary.

## The Disk Method

The disk method is a straightforward technique for finding the volume of a solid of revolution when the solid is formed by rotating a region around a horizontal or vertical axis. When using this method, the solid is divided into infinitesimally thin disks stacked along the axis of rotation.

### Setting Up the Disk Method

To apply the disk method, follow these steps:

1. Identify the function that defines the shape being revolved.
2. Determine the axis of rotation.
3. Set up the integral using the formula for the volume of a disk.
4. Evaluate the integral over the specified bounds.

The formula for the volume  $(V)$  using the disk method is given by:

$$V = \pi \int [f(x)]^2 dx$$

In this formula,  $f(x)$  is the function being revolved, and the integral is evaluated from the lower bound  $(a)$  to the upper bound  $(b)$  of the region being rotated.

### Example of the Disk Method

Consider the function  $f(x) = x^2$  being revolved around the  $x$ -axis from  $(x = 0)$  to  $(x = 2)$ . To find the volume of the solid formed, we set up the integral:

$$V = \pi \int_{\text{from } 0 \text{ to } 2} [x^2]^2 dx$$

This simplifies to:

$$V = \pi \int_{\text{from } 0 \text{ to } 2} x^4 dx$$

Calculating this integral yields:

$$V = \pi \left[ \frac{1}{5}x^5 \right]_{\text{from } 0 \text{ to } 2} = \pi \left( \frac{32}{5} \right) = \frac{32\pi}{5}$$

## The Washer Method

The washer method extends the disk method to situations where there is a hole in the solid. This method is particularly useful when revolving a region that is bounded by two functions. The volume is calculated by subtracting the volume of the inner disk from the volume of the outer disk.

## Setting Up the Washer Method

To apply the washer method, follow these steps:

1. Identify the two functions that bound the region.
2. Determine the axis of rotation.
3. Set up the integral using the formula for the volume of a washer.
4. Evaluate the integral over the specified bounds.

The formula for the volume  $(V)$  using the washer method is given by:

$$V = \pi \int [f(x)]^2 - [g(x)]^2 dx$$

Here,  $f(x)$  represents the outer function, and  $g(x)$  is the inner function, with the integral evaluated from  $(a)$  to  $(b)$ .

## Example of the Washer Method

Consider the functions  $f(x) = x^2$  and  $g(x) = x$ , rotated about the  $x$ -axis from  $x = 0$  to  $x = 1$ . The volume of the solid can be determined by setting up the integral:

$$V = \pi \int_{\text{from } 0 \text{ to } 1} [(x^2)^2 - (x)^2] dx$$

This simplifies to:

$$V = \pi \int_{\text{from } 0 \text{ to } 1} [x^4 - x^2] dx$$

Calculating this integral yields:

$$V = \pi \left[ \frac{1}{5}x^5 - \frac{1}{3}x^3 \right]_{\text{from } 0 \text{ to } 1} = \pi \left[ \left( \frac{1}{5} - \frac{1}{3} \right) \right] = \pi \left[ \frac{3 - 5}{15} \right] = -\frac{2\pi}{15}$$

## Applications of Washers and Disks Calculus
