Interpreting IR Spectra

Interpreting IR spectra requires a solid understanding of the principles of spectroscopy and the specific characteristics of molecular vibrations. Each peak in an IR spectrum corresponds to a specific vibrational mode of a chemical bond. The position and intensity of these peaks can provide valuable insights into the functional groups present in a molecule.

Common Functional Groups and Their IR Absorption Peaks

When interpreting IR spectra, chemists often refer to characteristic absorption ranges for common functional groups. Some examples include:

- O-H stretch: 3200-3600 cm^{-1} (broad peak for alcohols)
- C=O stretch: 1650-1750 cm^{-1} (sharp peak for carbonyl compounds)
- C-H stretch: 2800-3000 cm^{-1} (peaks for alkanes, alkenes, and aromatics)
- N-H stretch: 3300-3500 cm^{-1} (sharp peak for amines)

By recognizing these peaks, researchers can confirm the presence of specific functional groups and deduce the overall structure of the molecule being analyzed.
