Understanding Perimenopause

Perimenopause is the transitional phase leading up to menopause, which officially marks the end of a woman's reproductive years. This stage can begin in a woman's 30s or 40s and may last several years until menopause is reached. During perimenopause, the body experiences fluctuating hormone levels, particularly estrogen and progesterone, which can lead to various physical and emotional changes.

What Causes Perimenopause?

The primary cause of perimenopause is the natural decline in ovarian function. Duration of Perimenopause

Perimenopause can last anywhere from a few months to over a decade, with most women experiencing it for around four years. The duration and severity of symptoms vary widely
